FUNDS CUSTODY

Funds custody and clearing

Prepare, verify, authorize and prove exact unauthorized-debit and queue-custody corrections.

Where to go: /funds-custody

Access and authority

The current Funds Custody page is Admin-restricted in addition to module access. Backend maker/checker/reversal roles and write gates still govern each operation.

01 / Prepare a Finance batch

Before you begin: A Finance reference and CSV/XLSX containing a single Account or RRN column.

1. Import and seal scope

In Batch control choose Create controlled batch, select Account or RRN, and use the matching one-column template. Keep identifiers as text to preserve leading zeroes. Review validation, source owner/reference and hash. Correct invalid input in a new source file, not in sealed rows.

2. Verify Oracle evidence

Run Verify Oracle evidence. Wait for reconciliation and inspect execution-safe, special-review, blocked and no-action classifications. Open each selected row to inspect mapping, currency, amount and queue identity.

3. Arm the intended tranche

Select only proven intended rows. Read the current operating-window limit; the default protection window is 08:00-19:00 with at most 20 pending rows per tranche. Outside it, Arm all pending can select remaining eligible scope. The server's displayed limit is authoritative.

4. Submit the sealed selection

Review count, authorized value and reference, then Submit. Unarmed rows are not in the submitted payload. Move to Execution desk for checker review.

How to confirm success

A submitted payload identifies the exact selected effects and immutable source.

Stop and check

A created batch is not verified authority. Blocked/no-action rows must not be forced into execution.

02 / Investigate an account or RRN

Before you begin: An external account or RRN and supporting authorization if preparing a correction.

1. Resolve the identity

Open Account explorer. Search by external account or switch to RRN. Confirm the uniquely resolved internal account and the specific currency balance row. Inspect holds, liens, unauthorized debit, physical queued amount and queue rows.

2. Choose the operation deliberately

Full debit clears the complete physical unauthorized debit and includes the proven debit queues for that internal account and currency. Specific queue clearing uses the approved transaction amount/fees and exact queue identity. A true partial debit clearing intentionally retains that queue until its complete authority is released.

3. Prepare and verify

Use the offered controlled-batch action for the selected currency/scope. Follow verification, selection and submission in Batch control. Lookup and selection alone do not mutate Oracle.

How to confirm success

The controlled batch reflects the intended account, currency and operation mode.

Stop and check

Unknown queue currency, ambiguous mapping, or queued authority exceeding full debit blocks safe clearing. Explicit credit queues and other currencies remain outside full-debit scope.

03 / Repair residual queue custody

Before you begin: Evidence that unauthorized debit is already zero, plus a justified queue repair.

1. Inspect exact evidence

In Account explorer inspect the selected currency, physical queued amount and outstanding rows. A queue-only cleanup differs from a debit reduction.

2. Choose the eligible repair

Use exact queue-row removal when those debit rows still exist. An orphaned physical queue-amount reset is only eligible when no live debit queue rows remain in that currency. Create the controlled batch and reconcile it.

3. Submit and authorize

Review the zero-debit-effect payload, exact queue deletions/reset, reference and approval. Verify resulting evidence in Execution desk and Custody trail.

How to confirm success

The approved queue custody is corrected without reducing unauthorized debit again.

Stop and check

Do not reset a physical queue amount while live queue rows remain. Preserve this cleanup path for existing residues; it is not a substitute for correct full clearing.

04 / Review a submitted payload

Before you begin: A submitted payload, checker authority and supporting reference. Approval executes the mutation.

1. Review before approval

In Execution desk inspect maker/checker, source and payload hashes, account/internal account, currency, before/after debit values and every queue deletion/reset. A different authorized checker is normal practice; the explicit Admin exception permits self-approval where configured.

2. Approve and execute once

Confirm both application and Oracle write gates in the intended environment. Use Approve and execute only when the exact sealed effects are authorized. There is no later manual execute step. Live row/scope changes require reconciliation and a fresh approval.

3. Prove the outcome

Read terminal status, before/after evidence and exact affected queue keys. Full-clear post-validation rejects remaining in-scope debit queues and rolls back that transaction. Specific full-transaction clearing removes its approved exact queue, not unrelated rows.

How to confirm success

The execution has a proven terminal outcome and immutable evidence.

Stop and check

COMMIT UNCERTAIN or a timeout is a stop condition: verify actual database state with the owner before retrying, replacing or reversing. Old full-debit payloads that predate queue-inclusive clearing must be reconciled and approved afresh.

05 / Trace an outcome or eligible reversal

Before you begin: An account/RRN, batch/execution reference or approximate date.

1. Browse the chronology

Open Custody trail. Search the identifier and expand year, month/day and activity as available. Inspect actor, time, references, sealed intent and execution proof.

2. Reverse only if eligible

In Execution desk use rollback only when the recorded committed execution is eligible and your role permits it. Provide the exact reason and review the proposed compensating change. Do not assume this is an unconditional undo.

3. Verify and archive

Confirm the reversal result and linked custody event. Archive eligible completed/rolled-back Account Explorer batches to clear the active rail; archiving does not erase custody.

How to confirm success

You can reconstruct the original decision, effect and any compensating reversal.

Stop and check

Changed live state can make reversal unsafe. Do not edit or remove history to simplify the narrative.

06 / Review specific-record policy

Before you begin: Admin authority and an approved scope decision.

1. Inspect the policy

Read the specific-record clearing policy in Execution desk. It controls whether non-admin operators can prepare transaction-specific clearing; Admin remains eligible under the backend contract.

2. Change and confirm

Toggle only under the approved operating decision and verify its recorded custody event. Page visibility and backend operation authority remain separate.

How to confirm success

The policy is explicit and attributable.

Stop and check

Do not change a policy or write gate merely to bypass a blocked operation.

Something is blocking you?

Full-debit approval predates queue-inclusive clearing

Reconcile and submit a fresh payload, then obtain approval for the full current queue scope.

Queue scope changed after approval

Do not force execution. Re-read Oracle, reconcile and review a fresh payload.

Blocked or special review

Open the interpretation. Resolve mapping/currency/amount ambiguity with Finance and the database owner; special review requires explicit evidence-based justification.

Commit uncertain means stop

Preserve execution reference and logs. Have the database owner prove actual balance/queue state before any retry or reversal.

Write gates closed

Verify the intended environment and approved configuration with the owner; do not enable writes just to make the control usable.

Terms in plain language

Unauthorized debit

The physical pending debit amount being governed; unauthorized credit is outside this workspace.

Sealed payload

An immutable description of approved effects; changing scope needs new approval.

Compensating reversal

A separately governed action restoring eligible recorded effects, subject to current-state checks.
