NEXUS

Environment rollover

Prepare, test and execute a governed environment change with explicit scope and proof.

Where to go: /nexus?workspace=rollover

Access and authority

Environment rollover access; configuration and execution are role- and challenge-gated.

01 / Configure and test a rollover

Before you begin: Have an approved source/target environment and change plan.

1. Review the environment contract

Create/edit the intended environment, connection profiles, schemas and replacement rules. Check each source value and target value; empty or wrong targets can affect the wrong environment.

2. Test connections

Run the available environment and schema connection tests. Inspect results for every required connection. Saving a profile is not a successful test.

3. Review the execution scope

Read the current assessment/test evidence and intended changes before requesting authorization. Save changes, then repeat affected tests.

How to confirm success

The saved contract and fresh tests support the exact planned change.

Stop and check

Do not proceed with missing targets, ambiguous replacements or failed tests.

02 / Authorize and follow a rollover

Before you begin: Have the approved change window, fresh tests, reason and rollback/recovery owner.

1. Request the challenge

Select the intended action and review source/target and scope. Request the one-time-code challenge only when the gates permit it.

2. Confirm once

Enter the issued code for that challenge and execute once. Follow execution history and detailed outcomes rather than assuming the request succeeded.

3. Verify and follow up

Check target connectivity and application behavior through the approved change procedure. Review/set available reminders for follow-up and acknowledge them appropriately.

How to confirm success

Execution history and post-change checks show what actually changed.

Stop and check

If completion is uncertain, stop and verify actual state before retrying. A test does not perform the rollover.

03 / Manage obsolete contracts and reminders

Before you begin: Confirm the environment is no longer in operational use.

1. Review dependencies and history

Inspect the selected environment and existing execution/reminder records.

2. Use the provided control

Edit reminders or delete an obsolete contract only where allowed and after reading the confirmation. Verify the resulting list.

How to confirm success

The active configuration reflects the approved inventory.

Stop and check

Do not delete a contract to hide failed execution evidence.

Something is blocking you?

OTP expired or gate blocked

Correct the failed prerequisite and request a fresh challenge for the same verified scope.

Test failure

Review the exact schema/connection result with the owner; do not weaken controls to continue.

Terms in plain language

Rollover

A controlled change from one environment/configuration to another.
